

Contribution Journal

Ranveer Chand

I downloaded the L04 notebook file and uploaded it to Google Colab, then shared it with everyone in the group through their emails, so we all had access to the same file. We used GroupMe to communicate and agreed that everyone would run through all the cells on their own first to get familiar with the lab. Then for the experimentation section at the end, we worked together to complete each experiment and fill in the knowledge check answers in the markdown cells. After that, I put together a Word document to collect and record everyone's contributions and another word document for the group's reflection journals. Since I'm the one submitting for the group, I downloaded both the completed notebook and the contribution journal. Then I created a new repository on GitHub for this course and created a new folder for the L04 lab and committed all the files to it.

I collaborated with my teammates over GroupMe to establish a clear plan for the lab. I focused on analyzing the notebook instructions first to understand of both the data observations and the coding requirements. After executing the Titanic dataset visualisations and completing the experimentation cells, we focused on the reflection section, evaluating how these specific data models behave and considering how these exact exploratory techniques apply to other analytical scenarios.

Using GroupMe, we coordinated with each other and decided our best approach was to first to see what the lab was asking from us, both in observing. We then decided to complete the project in sections individually, and then comparing each others models, seeing if we were having similar results and observations. We worked through it in this fashion all the way to the end. We then came to similar conclusions about the lab, seeing what could be different going forward.

I took on the 'Data Detective' role for our group, focusing on digging into the charts and data structure. I helped the team understand that our data was highly imbalanced because of the low survival rate, meaning any future AI model we built would be biased if we didn't adjust for it. I also spotted the major missing data gaps in the Age and Cabin columns right at the start, which sparked a great group discussion on data cleaning. Lastly, I handled the final Knowledge Check section, writing out our thoughts on the true purpose of EDA, the passenger survival profile, and why visual charts reveal patterns that simple numbers hide.
