

Contribution Journal

Ranveer Chand

For this lab, I started by uploading the notebook to Google Colab and sharing it with all group members, so everyone had access to it. My part was Part 1, Setup and Model Training, where I did the imports and training the logistic regression model on the Titanic dataset, so the rest of the notebook had a model to evaluate. I also discussed with our group about the reflection questions, and we wrote down what we settled on. Once everyone was done with their parts, I created all the required files, added their parts to the contribution word document, downloaded the files in the correct formats, made sure to rename everything correctly, and uploaded everything to my GitHub repository for submission.

For 07 lab, my task contribution was completing Task 3: Cross-Validation. I implemented the 5-fold cross-validation using `cross_val_score`, then checked that the model was evaluated across multiple different data splits, and generated the fold-level scores, the average accuracy all for stability. I explained why cross-validation needs a more reliable estimate. Then did Knowledge Check Question 1, explaining what can cause someone to miss an important message.

My job in Lab 07 was to complete and test Part 4. I did this by using CVs in order to split data into multiple folds in order to perform tasks and generate an average that reflects the data. After I completed this section, I talked to my group about my results and discussed any ideas we could do for the future and how we could incorporate what we learned from this lab further.

I contributed by implementing the confusion matrix to evaluate the logistic regression model beyond simple accuracy. I calculated the matrix using `confusion_matrix(y_test, y_pred)` and visualized it with a seaborn heatmap to make the results easier to interpret. This visualization allowed me to clearly identify the number of True Positives, True Negatives, False Positives, and False Negatives produced by the model. By analyzing these values, I gained a deeper understanding of how the model behaves, specifically where it performs well and where it makes mistakes.
